Many studies have been done around the world to estimate how often ADHD is present in children. Averaged across these studies, it is estimated that approximately 5.3% of children worldwide have ADHD.

Research findings indicate that roughly 22% of children with ADHD have no ADHD symptoms when they reach young adulthood.

For a long period, only children got a diagnosis of ADHD. Currently, ADHD is believed to be present in 2.8% - 4.4% of adults.

Especially when persisting in adulthood, people with ADHD may develop additional psychiatric or physical conditions.
